## Area 1: Model-Free Prediction (MC & TD Methods)

---

### Textbook Exercises (Sutton & Barto, 2nd Ed.)

#### Chapter 5: Monte Carlo Methods

Priority exercises: 5.1–5.6, and especially **5.12** (programming).

| Ex.         | Description                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------|
| 5.1         | Analyze why value function plots for blackjack show jumps at certain states                      |
| 5.2         | Compare bias properties of every-visit and first-visit MC estimators                             |
| 5.3         | Draw and describe the backup diagram for Monte Carlo estimation of $Q(s, a)$                     |
| 5.4         | Modify MC ES pseudocode to use incremental mean updates instead of storing all returns           |
| 5.5         | Calculate both first-visit and every-visit estimator types on a concrete example                 |
| 5.6         | Derive importance sampling equations for action value estimates $Q(s, a)$                        |
| 5.7         | Explain the behavior of MSE in weighted importance sampling at the start of learning             |
| 5.8         | Determine variance properties of the every-visit MC estimator                                    |
| 5.9         | Modify the off-policy MC algorithm using incremental update formulas                             |
| 5.10        | Derive the recursive weighted-average update rule                                                |
| 5.11        | Explain why the importance sampling ratio starts from $t + 1$ in off-policy control              |
| <b>5.12</b> | <b>Racetrack problem:</b> Implement MC control for a racetrack gridworld with noisy acceleration |

#### Chapter 6: Temporal-Difference Learning

Priority exercises for prediction: 6.1, 6.2, 6.3, 6.4, 6.5, 6.6.

| Ex. | Description                                                                 |
|-----|-----------------------------------------------------------------------------|
| 6.1 | Derive the telescoping sum identity for TD errors (fundamental)             |
| 6.2 | The “buffet” thought experiment—explain when TD outperforms MC              |
| 6.3 | Compute value updates after the first episode of the 5-state random walk    |
| 6.4 | Analyze how different $\alpha$ values affect TD vs. MC performance          |
| 6.5 | Investigate how increasing learning rate affects MSE over multiple episodes |
| 6.6 | Describe methods for computing the exact values in the random walk MRP      |

## Chapter 7: $n$ -step Bootstrapping

Both exercises are essential. Exercise 7.2 gives hands-on experience with the bias-variance spectrum.

| Ex. | Description                                                                                                            |
|-----|------------------------------------------------------------------------------------------------------------------------|
| 7.1 | Show the $n$ -step return error can be written as a sum of TD errors                                                   |
| 7.2 | <b>Programming:</b> Compare $n$ -step TD methods for different $n$ on the 19-state random walk, reproducing Figure 7.2 |

## University Assignments

| Assignment                     | What You Do                                                                                                                             |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| David Silver’s Easy21 (UCL)    | The gold standard. 5 parts: implement Easy21 env, MC control, SARSA( $\lambda$ ), linear FA, discussion. <a href="#">Assignment PDF</a> |
| Georgia Tech CS 7642 Project 1 | Reproduce Sutton (1988) original TD experiments on bounded random walk. <a href="#">Course page</a>                                     |
| Stanford CS234 Module 3        | TD policy evaluation, batch MC vs batch TD. <a href="#">Course page</a>                                                                 |

## Mini-Projects

### Project A: MC vs TD(0) Random Walk Comparison

Implement a configurable  $N$ -state random walk MRP (support  $N = 5, 19, 99$ ). Implement first-visit MC prediction and TD(0) prediction. Reproduce Figure 6.2 from Sutton and Barto: plot RMS error vs. episodes for TD(0) with  $\alpha \in \{0.05, 0.1, 0.15\}$  and constant- $\alpha$  MC with  $\alpha \in \{0.01, 0.02, 0.04\}$ . Reproduce Example 6.3 (batch updating). Extend to 19 states and reproduce Figure 7.2.

*Deliverables:* Four publication-quality figures, a written analysis (1–2 pages) of the bias-variance tradeoff observed.

### Project B: Blackjack Policy Evaluation Showdown

Use Gym’s Blackjack-v0 environment. Implement first-visit MC, every-visit MC, TD(0), and  $n$ -step TD prediction for the fixed policy: stick on 20 or 21, hit otherwise. Measure convergence speed. Produce 3D surface plots of the value function at 10K, 100K, and 500K episodes.

## Key Coding Resources

- [Denny Britz RL Repository](#) – MC/TD notebooks with starter code and solutions
- [Shangdong Zhang Figure Reproductions](#) – Python reproductions of nearly every textbook figure
- [Udacity Deep RL MC Notebook](#)

## Recommended Sequence

1. Read S&B Ch 5.1–5.5, do exercises 5.1–5.6
2. Code Denny Britz MC Prediction notebook (Blackjack)
3. Read Ch 6.1–6.3, do exercises 6.1–6.6
4. Code Mini-Project A (random walk, Figures 6.2 and 7.2)
5. Read Ch 7.1–7.2, do exercises 7.1–7.2
6. Complete Easy21 Parts 1–3

## Area 2: Model-Free Control (SARSA, Q-Learning, On/Off-Policy)

### Textbook Exercises (Chapter 6)

Priority: 6.6–6.7 (Windy Gridworld + extensions), 6.9 (Expected SARSA on cliff walking), 6.11–6.12 (why Q-learning is off-policy; greedy SARSA vs Q-learning), 6.14 (maximization bias / Double Q-learning).

| Ex.  | Description                                                                                 |
|------|---------------------------------------------------------------------------------------------|
| 6.6  | Implement SARSA on Windy Gridworld (Example 6.5); plot episodes vs time steps               |
| 6.7  | Extend 6.6 with King’s moves (8 actions) and stochastic wind                                |
| 6.8  | Derive the relationship between returns and action-value estimates through TD decomposition |
| 6.9  | Programming: Compare SARSA, Q-learning, and Expected SARSA on cliff walking                 |
| 6.10 | Why Q-learning’s policy (argmax) differs from its behavior policy ( $\epsilon$ -greedy)     |
| 6.11 | Explain precisely why Q-learning is classified as off-policy control                        |
| 6.12 | “If action selection is greedy, is Q-learning exactly the same as SARSA?”                   |
| 6.13 | Explore double learning applied to Expected SARSA                                           |
| 6.14 | Programming: Maximization bias problem, Q-learning vs Double Q-learning                     |

### University Assignments

| Assignment             | What You Do                                                                  |
|------------------------|------------------------------------------------------------------------------|
| Easy21 Parts 3–5       | SARSA( $\lambda$ ) with eligibility traces, linear FA comparison, discussion |
| Stanford CS234 Asgn. 2 | Linear Q-learning then full DQN on Atari. <a href="#">Course page</a>        |
| Berkeley CS285 HW3     | DQN + Double DQN on LunarLander and Ms. Pac-Man. <a href="#">Course page</a> |

### Classic Environments to Implement

#### Cliff Walking (Example 6.6)

4×12 grid. Start at bottom-left, goal at bottom-right. The bottom row between start and goal is a “cliff”—stepping on it gives reward  $-100$  and resets to start. Every other step gives  $-1$ . This is THE canonical demonstration of on-policy vs off-policy behavior. SARSA accounts for its own exploration noise; Q-learning ignores it.

Implement SARSA, Q-learning, and Expected SARSA. Plot sum-of-rewards per episode for all three algorithms over 500 episodes, averaged over 100 runs.

### Windy Gridworld (Example 6.5)

7×10 grid with wind columns. Implement SARSA with 4 actions, then extend to King's moves (8 actions), stochastic wind. Plot timesteps vs episodes completed.

### Taxi-v3 (Gymnasium)

500 discrete states. 6 actions. Compare Q-learning, SARSA, and Expected SARSA convergence rates and final win rates. [Environment docs](#).

### Maximization Bias / Double Q-Learning (Example 6.7)

Implement Q-learning (observe overestimation) and Double Q-learning (observe correction). Plot % of left actions taken from start state over episodes.

## Mini-Projects

### Project 1: TD Control Benchmark

Implement SARSA, Expected SARSA, Q-learning, and Double Q-learning from scratch (no RL libraries). Benchmark on FrozenLake-v1 (4×4 and 8×8, slippery=True), CliffWalking-v0, and Taxi-v3. For each algorithm × environment: run 100 independent trials, 1000 episodes each. Vary  $\epsilon \in \{0.01, 0.05, 0.1, 0.2\}$  and  $\alpha \in \{0.1, 0.3, 0.5\}$ . Produce heatmaps of final average return.

### Project 2: Safety-Aware Navigation

Design a custom 10×10 gridworld with danger zones (−50 but non-terminal) and cliffs (−100, reset). Demonstrate SARSA avoids danger zones during training while Q-learning finds the shorter but riskier path. Visualize learned Q-value heatmaps and policy arrows.

## Key Coding Resources

- [Denny Britz SARSA/Q-learning notebooks](#)
- [Cliff Walking implementations](#)
- [Windy Gridworld implementations](#)
- [RL Sketchpad – Ch. 6 figure reproductions](#)

## Recommended Sequence

1. Read S&B Ch 6.4–6.5 (SARSA, Q-learning). Do exercises 6.8, 6.11, 6.12
2. Implement Windy Gridworld (6.6–6.7)
3. Implement Cliff Walking—reproduce Example 6.6
4. Implement Double Q-learning (6.14) and Taxi-v3
5. Complete Easy21 all parts
6. Bridge to deep RL with CS285 HW3 or CS234 Assignment 2

## Area 3: Deep Learning Foundations

### University Assignments

| Assignment                    | What You Do                                                                                                                                                                |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CS231n Assignment 1           | k-NN, SVM, Softmax, Two-layer net—all from scratch in NumPy on CIFAR-10. <a href="#">Assignment page</a>                                                                   |
| CS230 Section 3 Exercises     | Hand-worked backprop through computation graphs. <a href="#">Exercises PDF</a>                                                                                             |
| Andrew Ng’s DL Specialization | Course 1 Weeks 2–4: logistic regression, 1-hidden-layer net, $L$ -layer net from scratch. Course 2 Week 1: L2 reg, dropout, gradient checking. <a href="#">Course page</a> |
| CS229 Problem Set 1           | Logistic regression, gradient/Hessian derivation, Newton’s method vs GD. <a href="#">PDF</a>                                                                               |

### Hand-Computation Exercises (Do on Paper)

1. **Matt Mazur’s Step-by-Step Example:** 2-input, 2-hidden, 2-output net with concrete numbers. Full forward+backward pass. [Link](#)
2. **Single-neuron logistic regression:** Derive  $\partial L / \partial w$  showing the form  $(\sigma(z) - y) \cdot x$
3. **Two-layer network with MSE:** Derive all four gradient terms  $\partial L / \partial W_2$ ,  $\partial L / \partial b_2$ ,  $\partial L / \partial W_1$ ,  $\partial L / \partial b_1$
4. **ReLU vs. Sigmoid gradient flow:** Repeat exercise 3 with ReLU. Notice why ReLU mitigates vanishing gradients
5. **Softmax + Cross-Entropy:** Show gradient simplifies to  $(\text{softmax}(z) - y_{\text{one-hot}})$

### From-Scratch Projects

#### Project 1: Linear Regression from Scratch

Pure NumPy. Implement forward pass ( $\hat{y} = Xw + b$ ), MSE loss, gradient computation, and gradient descent update loop. Compare with the closed-form solution (normal equation). Extend to batch, stochastic, and mini-batch gradient descent.

#### Project 2: Logistic Regression from Scratch

Binary classifier on `make_moons`. Implement sigmoid, binary cross-entropy, backward pass, training loop. Visualize decision boundary at different epochs. Add L2 regularization and observe changes.

#### Project 3: Karpathy’s Micrograd (Rebuild It)

The single best exercise for understanding backpropagation and autograd. Build a scalar-valued automatic differentiation engine ( $\sim 100$  lines of Python). Implement a `Value` class, `backward()`

using topological sort, then `Neuron`, `Layer`, and `MLP` classes.

- Repository: [github.com/karpathy/micrograd](https://github.com/karpathy/micrograd)
- Video lecture (2+ hours): [karpathy.ai/zero-to-hero.html](https://karpathy.ai/zero-to-hero.html)

### Project 4: Two-Layer Neural Network from Scratch

Full NumPy implementation on MNIST. Implement parameter initialization, forward pass, cross-entropy loss, backward pass, and mini-batch training loop. Extensions: ReLU activation, L2 regularization, dropout, momentum, and Adam optimizer.

### Project 5: Michael Nielsen’s 74-Line Network

Work through Chapters 1–3 of [neuralnetworksanddeeplearning.com](https://neuralnetworksanddeeplearning.com). Classifies MNIST digits at >96% accuracy with no frameworks.

### Intuition-Building Mini-Projects

- **Loss Landscape Visualization:** Visualize the loss surface along two random directions in parameter space. Reference: [Li et al., 2017](#)
- **Gradient Flow Monitor:** Track gradient magnitudes per layer. Compare sigmoid (vanishing) vs. ReLU (healthy) vs. tanh. Add batch normalization.
- **Optimizer Comparison:** Implement vanilla SGD, momentum, RMSProp, Adam on the Rosenbrock function. Plot trajectories on contour plots.
- **Overfitting Laboratory:** Fit progressively larger networks on 20 points from a noisy sine wave. Then add L2, dropout, early stopping one at a time.

### Recommended Sequence

1. Hand-compute backprop (Matt Mazur, CS230 exercises)
2. Implement logistic regression from scratch
3. Build micrograd—the most important single exercise
4. CS231n Assignment 1 (two-layer net portion)
5. Nielsen Chapters 1–3

## Area 4: PyTorch & Automatic Differentiation

### Official PyTorch Tutorials (In Order)

| 7     | <b>DAVI on combinatorial puzzle</b>               | 15-puzzle or 2×2 Rubik's cube |

### Key Concepts

#### Target Networks

If the same network generates both the prediction and the target, every update shifts the target, creating a feedback loop. The target network  $\theta^-$  freezes the target for  $N$  steps. The DQN loss becomes:  $L(\theta) = E \left[ (r + \gamma \max_{a'} Q(s', a'; \theta^-) - Q(s, a; \theta))^2 \right]$

## Experience Replay

Online RL training data is (a) temporally correlated and (b) non-stationary. Both properties violate the i.i.d. assumption of SGD. Experience replay stores transitions  $(s, a, r, s')$  in a buffer and samples mini-batches uniformly at random, breaking both correlations.

## The Deadly Triad

Function approximation + bootstrapping + off-policy learning can cause divergence. DQN mitigates this with target networks and experience replay, but does not fully solve it.

## Deep Approximate Value Iteration (DAVI)

Generate training data by scrambling from the goal state. Train a neural network to predict cost-to-go. Use that network as a heuristic in A\* search. This is the approach in Prof. Agostinelli's DeepCubeA paper.

## Key Implementation References

- [CleanRL DQN](#)—single-file, most readable DQN

- [Daniel Takeshi: Atari Preprocessing](#)

## Recommended Sequence

1. Read Sutton & Barto Ch. 9–11 (function approximation theory)
2. Read DQN papers (2013, then 2015 Nature)
3. Implement tabular Q-learning on FrozenLake, then linear FA on CartPole
4. Implement full DQN on CartPole, then LunarLander
5. Read DeepCubeA paper, study the [GitHub repo](#)
6. Implement simplified DAVI on a combinatorial puzzle
